Q: How do I calibrate my DO probe with the YSI 4010 MultiLab meter?

A: Unless otherwise specified in company or site-specific procedures, specifications, and regulations, a water vapor-air saturated calibration should be sufficient for probe calibration.

Why calibrate?

Standard Methods 5210 for Biological Oxygen Demand, 23rd Edition, states to calibrate the DO probe daily by following the manufacturer's calibration procedure. It also recommends making frequent calibration checks daily to ensure accurate DO readings.

The following will outline the calibration method options for PC-BOD and the YSI 4010 MultiLab meter. YSI recommends that to best evaluate the quality of the calibration, it is pertinent to check the quality of the calibration record as well as the accuracy of the calibration via an altitude chart.

Above all, it is pertinent that operators follow company and/or site-specific procedures, specifications, and regulations. The below information may be considered when developing appropriate operating procedures.

Calibration Methods

- Calibration in water vapour-saturated air
 - Includes reference to altitude chart
- Calibration by a comparison measurement, e.g. Winkler Titration
- 1. Calibration in water vapour-saturated air

Unless otherwise specified in company or site-specific procedures, specifications, and regulations, a water vapor-air saturated calibration should be sufficient for probe calibration.

This calibration method requires a 300mL BOD bottle containing ~40mL of clean water (or ~1inch of clean water in any BOD bottle). The DO probe will sit on the BOD bottle with a seal created between the bottle and the probe; the sensor must not be immersed in the water. The probe should stabilize in the bottle for approximately 15 minutes, to allow the air to be saturated with water vapour and the sensor to adapt to ambient temperature.

MANTECH FAQ

Once the probe is stable, complete the calibration by doing the following steps:

- a. Press <CAL> and then <ENTER>. The measured value is checked for stability. While the stability is being verified, the display will show [AR].
- b. Once the stabilization is verified, the meter will beep, and the calibration record and evaluation are displayed.

The calibration value is automatically evaluated after each calibration. For evaluation, the slope of the sensor is compared to the slope of an ideal sensor, using the following equation: $S = S_{semsor}/S_{ideal}$. An ideal sensor has a slope of 1.

There are four different classifications of the calibration evaluation, summarized in the Table 1 below:

| Calibration Record | Relative Slope | | | |
|--------------------|------------------------------------|--|--|--|
| +++ | 0.94 < S < 1.06 | | | |
| ++ | 0.92 < S < 0.94 or 1.06 < S < 1.08 | | | |
| + | 0.90 < S < 0.92 or 1.08 < S < 1.10 | | | |
| Error | S < 0.90 or S > 1.10 | | | |

Table 1: Calibration Evaluation

(Xylem Inc. (2018). *MutliLab* 4010-3W Operating Manual ba76194e 03 07/2018. OH.)

Ideally, the calibration record will display +++, which indicates that the sensor is measuring closest to an ideal sensor. If the calibration record is displaying less than +++, recalibrate, or compare the displayed result to the altitude chart shown in Table 2. If the displayed value matches the chart's value, then the calibration is valid, however, the sensor may need replacement soon (i.e. new sensor cap or membrane). It is good practice to always compare the measured value against the attitude chart, even if the calibration record displays +++.

- c. To view the measured calibration value, press <F1> to return to the DO display.
- d. Press <M> to change the display mode to % Saturation. Use the chart in Table 2 to verify the measured value.
 - i. If the measured value doesn't fall in the range specified in the chart, consider recalibrating or changing the sensor (i.e. change the sensor cap or membrane).
- e. Press <M> again to change the display back to mg/L. The display must be in units of mg/L to run BOD analysis.

*The internal barometer on the YSI 4010 MultiLab meter is calibrated upon manufacturing and is designed to last the lifespan of the barometer sensor. The sensor is very stable and can last many years. Standard Methods does not specify a requirement for an adjustable barometer for dissolved oxygen measurements or biological oxygen demand testing.

MANTECH FAQ

2. Calibration by a comparison measurement, e.g. Winkler Titration

Unless otherwise specified in company or site-specific procedures, specifications, and regulations, a Winkler Titration calibration is not recommended. A water vapor-air saturated calibration should be sufficient for probe calibration.

This method can be used to compare and adjust the measured value of the sensor against the nominal value of a comparison solution by applying a correction factor. The current correction factor is documented in the sensor menu and calibration record as *Factor* = x.xxx.

Complete a calibration by comparison measurement using the following steps:

- a. Immerse the sensor in the reference solution.
- b. Start the calibration by pressing <CAL> on the meter, followed by <ENTER>.
- c. The measured value is checked for stability. While the stability is being verified, the display will show [AR].
- d. Once the stabilization is verified, the meter will beep, and display the current reading.
- e. Use the up and down arrows to adjust the current reading to the nominal value of the reference. Press <ENTER> to apply the nominal value.
- f. The meter will switch to the measured value display and [Factor] is shown on the screen to indicate that the correction factor is applied to subsequent measurements.
